

Lecture 21: Process modeling & balance laws

- Process modeling, structure and methodology
- Balance laws
 - Mass balances
 - Mass balances for multi-component systems

Book: 10.4, 11.1-11.4

What are process modeling and balance laws used for?

Process modeling & balance laws:

- Basically, modeling of anything that changes in the physical world.
- In this context, we will be concerned with **fluids** (liquids and gas) in (chemical) **process systems**

Autoignition of hydrogen in a turbulent hot air coflow

Process modeling: Structure and methodology

- Goal of process modeling: **Construct mathematical models of the process under study.**
- These mathematical models consists of process variables (**variables** and **parameters**) and the **equations** that link these

Process

Process variables

(variables and parameters)

- **Level**
 - Variability: Variable
 - Symbol: h
 - Value: 1.1
 - Unit: m
 - ...
- **Area**
 - Variability: Parameter
 - Symbol: A
 - Value: 2.2
 - Unit: m^2
 - ...
- ...

Process equations

$$\frac{dh}{dt} = \frac{1}{A} (q_i - q_o)$$

$$q_o = C\sqrt{p - p_0}$$

$$p = p_0 + \rho gh$$

Number of equations must match number of (unknown) variables.

Process equations

- Balance laws

- Mass
- Momentum
- Energy
- ...

- Constitutive equations

- For (generalized) flows
- Thermodynamic equations of state (e.g. ideal gas law)
- Phenomenological relationships (e.g. between friction force and flow in a pipe)
- ...

- Constraints

- Geometric relationships
- Equilibrium conditions
- ...

Also called «closure relations» as they «close» the balance laws (such that #equations = #variables)

Example Tank:

$$\frac{dh}{dt} = \frac{1}{A} (q_i - q_o)$$

$$q_o = C\sqrt{p - p_0}$$

$$p = p_0 + \rho gh$$

$$V = Ah$$

Process variables

- Thermodynamic state variables

- Mass, pressures, levels, ...
- Velocities
- Temperatures
- ...

- (Generalized) flows

- Transport (single phase)
- Exchange (between phases)
- Sources (reactions)
- ...

- Phenomenological coefficients

- Viscosity
- Reaction rates
- Valve constants
- ...

- Geometric dimensions

- Lengths, Areas, Volumes
- ...

Example Tank:

h, ρ, p, p_0

q_i, q_o

C, g

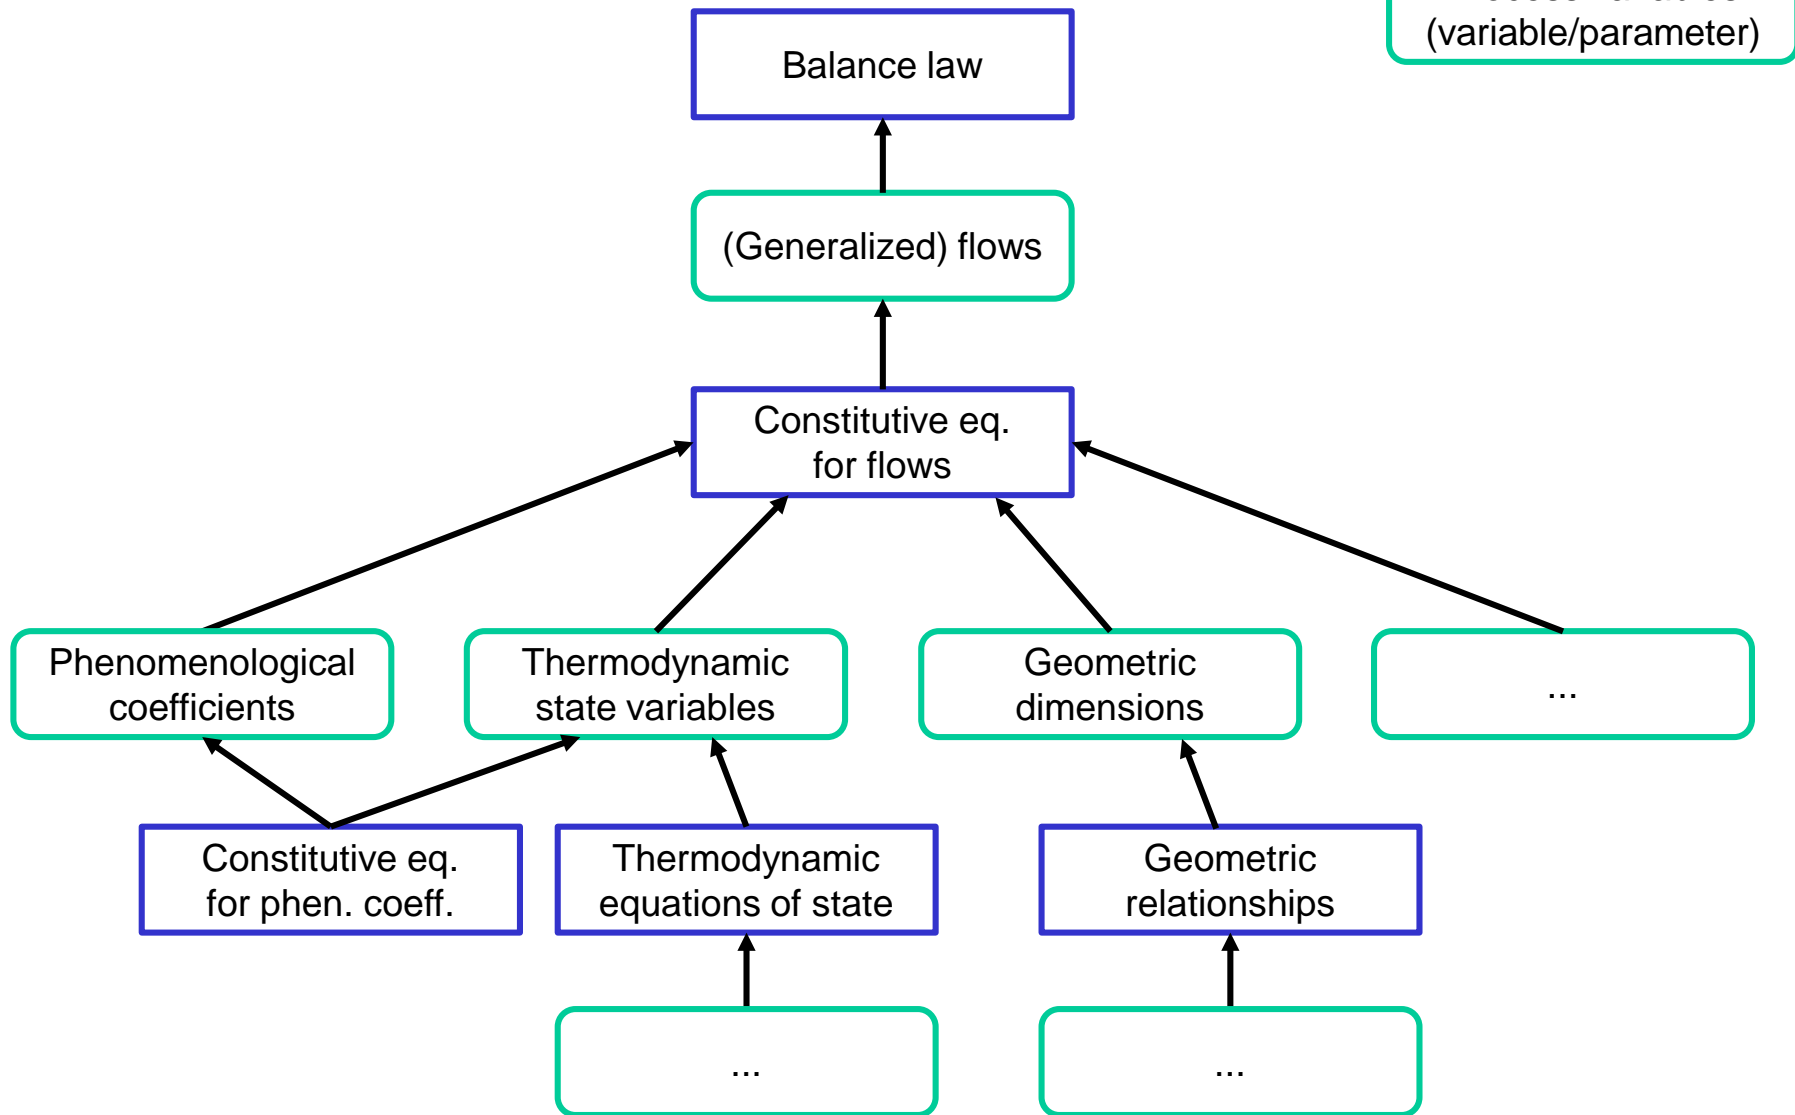

A

$$\frac{dh}{dt} = \frac{1}{A} (q_i - q_o)$$

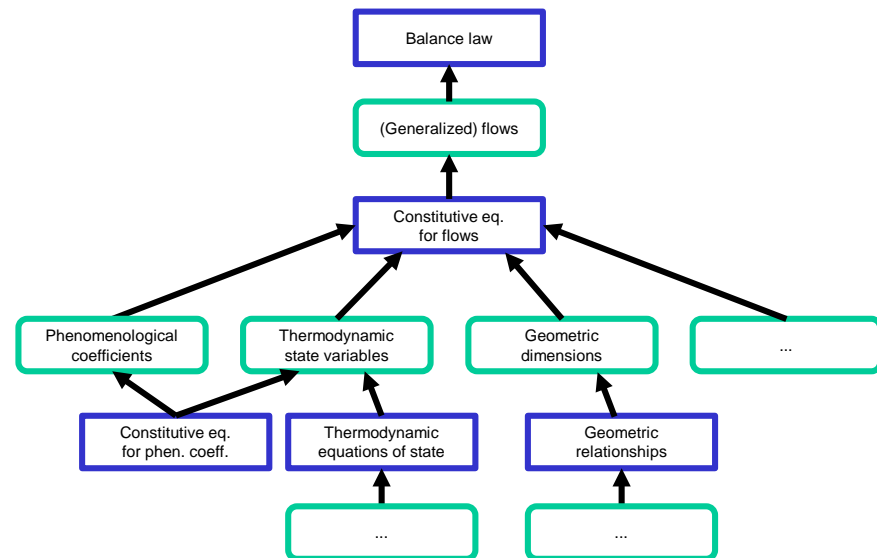

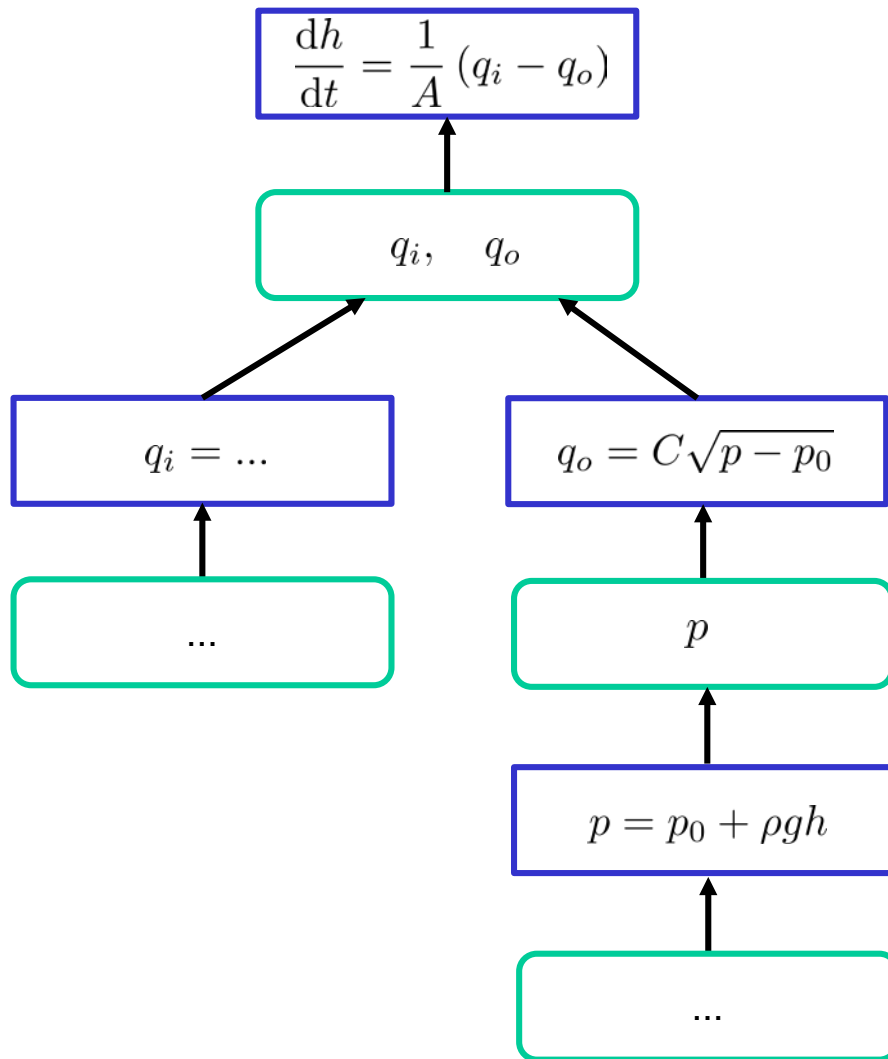

$$q_o = C\sqrt{p - p_0}$$

$$p = p_0 + \rho gh$$

Structure of process models

Example: Tank

BALANCE LAWS

Physical balance principles are based on

Conservation laws

That a physical property is *conserved*, means that it will remain constant in a closed system

The following physical quantities are conserved:

- Mass
- Energy
- Momentum (norsk: impuls)
 - Linear and angular

No one has ever observed that conservation laws have been violated

- Conservation laws are exact laws

The basic physical principles

Consider a volume consisting of a **fixed** number of fluid particles, with total mass m , total momentum \vec{p} and total energy E . From basic physics (conservation laws), we know the following principles hold:

- Conservation of mass (mass balance):

$$\frac{dm}{dt} = 0$$

- Newton's second law (momentum balance)

$$\frac{d\vec{p}}{dt} = \vec{F}$$

Also holds for angular momentum, $\vec{h} = \vec{r} \times \vec{p}$:

$$\frac{d\vec{h}}{dt} = \vec{r} \times \vec{F} = \vec{T}$$

- First law of thermodynamics (conservation of energy, energy balance):

$$\frac{dE}{dt} = \dot{Q} - \dot{W}$$

Rate of heat flowing into volume from surroundings $\rightarrow \dot{Q}$
 \dot{W} Rate at which work is done by the body at surroundings

State variables for process systems

- What variables are relevant as state variable(s) for balance laws based on conservation of mass (that is, mass balances)?
 - Mass
 - Density
 - Moles, and mole concentration
 - Derived quantities: Pressure, level, ...
 - (number of particles, etc.)
- For energy balances:
 - Internal energy
 - Temperature
- For momentum balances
 - Linear or angular momentum
 - Velocities

Extensive and intensive properties

- We must choose properties (thermodynamic variables) to describe our process, and these are either *intensive* or *extensive*
- Intensive properties are scale invariant (does not change if we divide a volume in two), while extensive variables are proportional to amount of material
- In this course, we use mostly *mass-intensive* properties/variables (that is, we measure amount of material with mass):

Extensive properties	Symbol	Unit	Intensive properties	Symbol	Unit
mass	m	kg	1	-	-
volume	V	m ³	specific volume	v	m ³ /kg
internal energy	U	J	specific internal energy	u	J/kg
enthalpy	H	J	specific enthalpy	h	J/kg
entropy	S	J/K	Specific entropy	s	J/K/kg

- What alternatives are there to mass-intensive?
- Is temperature an intensive or extensive property? Pressure? (yes and no...)

P-h-diagram for water

The concept of control volume

- We use a control volume for separating what we are interested in from the rest of the world (surroundings)
- Generally, material flow into (or out of) the control volume, across the surface

Extensive Property B of one particle

$$dB = \rho(\mathbf{x})\beta(\mathbf{x}, t)dV$$

Summed over all particles in $V_c(t)$

$$B = \iiint_{V_c(t)} \rho(\mathbf{x})\beta(\mathbf{x}, t)dV$$

- We are interested in
 - knowing how the extensive property B varies inside the control volume
 - **or** (equivalently?) how the intensive property $\beta(\mathbf{x}, t)$ varies inside the volume
- Control volumes can move or change shape, but we will assume they are **fixed** (more on this in fluid mechanics)

Lumped vs distributed modeling

- If we do *lumped modeling*, we assume that intensive properties are constant (or averaged) over the control volume

$$B = \iiint_{V_c} \rho \beta(\mathbf{x}) dV = \iiint_{V_c} \rho \bar{\beta} dV = \bar{\beta} \iiint_{V_c} \rho dV = m \bar{\beta}$$

- The balance laws used for lumped modeling are the *integral* (or *macroscopic*) balance laws
 - Formulated for extensive (e.g. mass), or averaged intensive (e.g. average temperature), variables
- The alternative to lumped modeling is *distributed* modeling, where we are interested in how $\beta(\mathbf{x}, t)$ varies as a function of position \mathbf{x}
- The balance laws for distributed modeling are the *differential* balance laws

(This course: Mainly lumped modeling and integral balance laws)

The balance laws

- Assume a **fixed** control volume (of arbitrary size and shape), where fluid flows across the control volume

$$B = \iiint_{V_c} \rho \beta(\mathbf{x}, t) dV$$

- The general integral (macroscopic) balance law for B is

$$\frac{d}{dt} B = \left\{ \begin{array}{l} \text{transfer of } B \text{ through} \\ \text{surface } \partial V_c \text{ by} \\ \text{fluid flow (convection)} \end{array} \right\} + \left\{ \begin{array}{l} \text{other effects that} \\ \text{transfer } B \text{ into } V_c \\ \text{(indep. of fluid flow)} \end{array} \right\}$$

The balance laws

- **Mass balance** (without reactions/phase transfer)

$$\frac{d}{dt}m = \left\{ \begin{array}{c} \text{transfer of mass into} \\ V_c \text{ by fluid flow} \\ \text{across surface } \partial V_c \end{array} \right\}$$

- **Momentum** (note: momentum is a vector)

$$\frac{d}{dt}\mathbf{p} = \left\{ \begin{array}{c} \text{transfer of momentum into} \\ V_c \text{ by fluid flow} \\ \text{across surface } \partial V_c \end{array} \right\} + \left\{ \begin{array}{c} \text{generation of momentum} \\ \text{in } V_c \text{ due to forces} \\ \text{acting on } V_c \end{array} \right\}$$

- **Energy**

$$\frac{d}{dt}E = \left\{ \begin{array}{c} \text{transfer of energy into} \\ V_c \text{ by fluid flow} \\ \text{across surface } \partial V_c \end{array} \right\} + \left\{ \begin{array}{c} \text{transfer of energy into} \\ V_c \text{ by heat transfer} \\ \text{and by work} \end{array} \right\}$$

Mathematical formulation of convection

$$\frac{d}{dt}B = \underbrace{\left\{ \begin{array}{l} \text{transfer of } B \text{ through} \\ \text{surface } \partial V_c \text{ by} \\ \text{fluid flow (convection)} \end{array} \right\}}_{-\iint_{\partial V_c} \rho \beta \vec{v} \cdot \vec{n} dA} + \left\{ \begin{array}{l} \text{other effects that} \\ \text{transfer } B \text{ into } V_c \\ \text{(indep. of fluid flow)} \end{array} \right\}$$

- (draw blackboard)

Mathematical formulation of mass balance

- For mass, the intensive variable is $\beta(\mathbf{x}, t) = 1$ $B = \iiint_{V_c} \rho \beta dV$

$$\frac{d}{dt}m = \left\{ \begin{array}{l} \text{transfer of mass into} \\ V_c \text{ by fluid flow} \\ \text{across surface } \partial V_c \end{array} \right\} - \iint_{\partial V_c} \rho \beta \vec{v} \cdot \vec{n} dA$$

$$\frac{d}{dt}m = \frac{d}{dt} \iiint_{V_c} \rho dV = - \iint_{\partial V_c} \rho \vec{v} \cdot \vec{n} dA$$

- (Example: Flow in pipe)
- Often, we have one (or more) «point inflows» $w_{\text{in},i}$, and outflows $w_{\text{out},i}$. Then mass balance can be formulated as

$$\frac{d}{dt}m = \sum_i w_{\text{in},i} - \sum_i w_{\text{out},i}$$

- (Example: Tank)

Mass-type balance laws with generation

- Assume B is an extensive variable «equivalent to» mass
 - that is, mass of a component in a volume, or number of molecules of a component, number of particles, etc.
- These types of mass balance laws can have *internal generation*:

$$\frac{d}{dt}B = \sum_i W_{\text{in},i} - \sum_i W_{\text{out},i} + W_{\text{generated}}$$

- More generally, if the local rate of generation of B is r_B :

$$\frac{d}{dt}B = \frac{d}{dt} \iiint_{V_c} \rho \beta dV = - \iint_{\partial V_c} \rho \beta \vec{v} \cdot \vec{n} dA + \iiint_{V_c} r_B dV$$
