Exercise 2 - TTK4130 Modeling and Simulation

Camilla Sterud

Problem 2

There are three criteria that ust be fullfilled by the rational, proper transfer funtion H(s) for it to a positive real:

- 1. All the poles of H(s) have $Re(\lambda_i) \leq 0$.
- 2. $Re[H(j\omega)] \ge 0 \ \forall \ \omega \text{ s.t. } j\omega \text{ is not a pole of } H(s).$
- 3. If $j\omega_0$ is a pole of H(s), it is simple and $Res_{s=j\omega_0}[H(s)] > 0$.

 \mathbf{a}

$$H_1(s) = \frac{1}{1 + Ts}.$$

 $H_1(s)$ has a pole at $-\frac{1}{T}$, which has a neagtive real part for T>0.

$$Re[H_1(j\omega)] = Re[\frac{1}{1+Tj\omega}] = \frac{1}{1+\omega^2T^2} \ge 0 \quad \forall \omega.$$

 $H_1(s)$ is positive real

$$H_2(s) = \frac{s}{s^2 + \omega_0^2}.$$

 $H_2(s)$ has a pair of complex conjugated poles at $\pm j\omega_0$, which has a real part of zero. If we picture the phase plot of $H_2(j\omega)$, it will start out in 90° because of the zero in $\omega=0$. The complex conjugate pole pair will cause the phase to fall by 180°, making the phase end up at -90° . This means that $H_2(s)$ will always stay in the right half plane of the complex plane and we can conclude that $Re[H(j\omega)] \geq 0$.

$$Res_{s=j\omega_0}[H_2(s)] = \lim_{s \to j\omega_0} (s - j\omega_0) H_2(s) = \lim_{s \to j\omega_0} \frac{s}{s + j\omega_0} = \frac{1}{2} > 0.$$

 $H_2(s)$ is positive real

b

$$H_3(s) = \frac{s+a}{(s+b)(s+c)}, \quad b, c > 0.$$

 H_3 has two ploes in -b and -c, both with negative real parts.

We have several cases in need of consideration to decide for which a $H_3(s)$ is positive real. The poles in -b and -c will contribute to the phase with -180° . If a < 0, $H_3(s)$ will start out in the left half plane, so that can be excluded. If a > b, c the phase will fall below -90° before a can pull it up again by 90° . The only cases where $H_3(s)$ stays in the right half plane is if a = 0, thus stating out the phase plot in 90° , or if a < b + c.

This can also be seen by calculating the real part of $H_3(s)$:

$$Re[H_3(j\omega)] = \frac{abc + \omega^2(b+c-a)}{(\omega^2 + b^2)(\omega^2 + c^2)}$$

It is easy to see that this will only always be positive if the numerator stays positive for all ω , as the denominator will always be positive. This only happens in the same cases as mentioned above, so

 $H_3(s)$ is positive real for $0 \le a < b + c$

 \mathbf{c}

$$H_4(s) = \frac{s^2 + a^2}{s(s^2 + \omega_0^2)}, \quad a \ge 0.$$

The poles of $H_4(s)$ are at 0 and $\pm j\omega_0$, which are all at the imaginary axis with zero real part.

$$Re[H_4(j\omega)] = Re[\frac{a^2 - \omega^2}{j\omega(\omega_0^2 - \omega^2)}] = 0,$$

so criterion 2 is fullfilled.

$$Res_{s=0}[H_4(s)] = \lim_{s \to 0} s \frac{s^2 + a^2}{s(s^2 + \omega_0^2)} = \frac{a^2}{\omega_0^2} > 0 \quad \forall \, a \neq 0.$$

$$Res_{s=j\omega_0}[H_4(s)] = \lim_{s \to j\omega_0} (s - j\omega_0) \frac{s^2 + a^2}{s(s^2 + \omega_0^2)} = \frac{\omega_0^2 - a^2}{2\omega_0^2} > 0, \quad a \in (-\omega_0, \omega_0)$$

 $H_4(s)$ is positive real for $0 < |a| < |\omega_0|$

 \mathbf{d}

$$T\dot{y} = -y + u \Rightarrow f(y, u) = \frac{1}{T}(-y + u)$$

The storage function must fulfill

$$\dot{V} = \frac{\partial V}{\partial y} f(y, u) = u^T y - g(y) \quad \forall u, \quad g(y) > 0.$$

Choose the storage function to be

$$V = \frac{1}{2}Ty^2$$

$$\dot{V} = Ty\dot{y} = y(-y+u)$$

$$\dot{V} = uy - y^2 \Rightarrow g(y) = y^2 > 0 \Rightarrow Passive$$

 \mathbf{d}

$$H(s) = \frac{(s+z_1)...(s+z_m)}{s(s+p_1)...(s+p_n)}, \quad Re(p_i) > 0, \ Re(z_i) > 0, \ n > m.$$

H(s) is rational and proper. Criterion 1 is fulfilled, all the poles of H(s) have negative real part, except for the one that is zero. The residual of the pole in zero is

$$Res_{s=0}H(s) = \frac{z_1...z_m}{p_1...p_n}.$$

Since complex poles and zeros of a transfer function always exist in complex conjugate pairs, and all p_i, z_i have positive real parts, the residual must be real and greater than zero.

This leaves only criterion 2, so

 $\underline{\underline{H(s)}}$ is positive real if and only if $Re[H(j\omega)] \ge 0$
